The 2-Minute Winning Pitch Script

0:00 - 0:30: The Hook & Problem

"Every year, organizations spend thousands of hours manually reviewing PDF resumes, while governments and universities lose millions to forged documents. Candidates are forced to re-upload the same credentials to hundreds of portals. We built **Sabi Vault**—a sovereign data infrastructure and decentralized identity platform that replaces static PDFs with programmable, tamper-proof API keys."

0:30 - 1:15: The Live Demo (Show, Don't Just Tell)

- *Action 1 (User Side):* "Here is the user vault. Files sync directly from the user's private Google Drive—we never hold raw files. I select 'Academics' and 'Finance' and generate a 7-day scoped API key."
- *Action 2 (Enterprise Side):* "Now I paste this API key into our recruiter portal alongside an uploaded job description. Watch what happens."
- *Action 3 (Verification & AI):* "The system fetches the structured data, runs an automated SHA-256 blockchain check to verify document integrity, and our multi-LLM gateway instantly ranks the applicant against the job requirements."

1:15 - 1:45: The Architecture & GovTech Model

"Sabi Vault uses a three-tier model: physical files stay in the user's cloud, structured text sits on country-specific database nodes for strict GDPR/NDPC compliance, and cryptographic hashes live on-chain. When organizations pay micro-transactions to query keys, smart contracts split the fee 60/40 between our platform and the sovereign government hosting the node."

1:45 - 2:00: The Vision

"We are turning static legal compliance into a sovereign, profit-generating data network for nations while giving users total ownership of their digital credentials."

Technical Defense Cheat-Sheet for Judges

Judge Question	**Plain-English Answer**	**Deep Technical Defense**
"Where are raw documents stored? Is this GDPR compliant?"	"We never store raw documents on our servers or on the blockchain."	"Files remain in the user's personal cloud via OAuth. Only parsed JSON text lives on localized PostgreSQL/Supabase database nodes within the user's home country, satisfying data residency laws."

"Why do you need blockchain if you already have a database?"	"The database holds readable text; the blockchain proves no one tampered with it."	"Databases can be altered by admins. We store a SHA-256 hash string on-chain upon upload or notary seal. When queried, we re-hash the data—if a single character was edited, the hashes won't match."
"What if an LLM hallucinates candidate qualifications?"	"The LLM only analyzes verified text; it doesn't invent data."	"We use a strict Retrieval-Augmented Generation (RAG) pipeline over structured JSON schemas. The LLM acts purely as an evaluator against the uploaded requirement document."
"What happens if your primary AI model goes down during bulk queries?"	"We built a multi-provider gateway with automatic failover."	"Queries route through an enterprise gateway configured with fallback providers (e.g., OpenAI, Anthropic, Gemini, or local open-source models) to ensure zero operational downtime."
"How do you handle un-notarized vs. legal documents?"	"We support a two-tier verification system."	"Tier 1 documents (bank statements) are hashed automatically upon cloud sync. Tier 2 documents (degrees/affidavits) require human notary verification before binding the seal and hash on-chain."

3 Tactics to Defeat Stage Fright

- **Anchor Your Eyes on Your Screen, Not the Judges:** When presenting, keep your focus on clicking through the demo. Looking at working software grounds your thoughts better than staring at an audience.
- **Use the "Pause and Point" Rule:** If you forget what to say, don't fill the silence with "um." Point at a specific element on your screen (e.g., *"As you can see right here on the blockchain status badge..."*) and read what is in front of you.
- **Let Your Teammates Share the Mic:** Divide the pitch into small pieces. Have one teammate handle the intro, you run the live demo and technical explanation, and your third teammate close with the market opportunity.
